Such curvature might easily result from increased pressure to which the thicker heads would be subjected in the leaf sheaths in which they are inclosed during the younger stages of growth. The presence of many crumpled awns also indicates that the broad heads experience unusual difficulties in emerging from the sheaths. Figure 11 shows one of these crumpled awns on one of the lower spikelets. The greater pressure and increased friction of the broad heads in the leaf sheaths may also be responsible for differences in the rachis. The joints of the rachis of the broad-seeded variation are shorter, thicker, and more curved than those of the ordinary wild wheat. That so many differences in the spikelets and rachis should arise as direct mechanical results of increasing thickness of the seed seemed rather improbable when the idea at first suggested itself, but parallel differences were found to occur in the domesticated types of wheat. In some of the so-called Sonora wheat growing in a neighboring field it was noticed that some of the heads had small, narrow spikelets near the base. Such spikelets not only had the same general shape as those of the wild wheat, but had the glumes straight sided and fitted together in the same way as in the wild wheat. Even more interesting was the fact that these narrow spikelets were accompanied by a marked elongation...
